

AI Interview Coach: Project Statement

Problem Statement

Traditional interview preparation relies heavily on self-assessment or manual feedback from mentors, which can be subjective, inconsistent, and difficult to access at scale. Candidates often struggle to identify weaknesses in communication, confidence, eye contact, speaking pace, filler word usage, and answer quality, resulting in poor interview performance.

The objective of this project is to develop an AI-powered Interview Coach that automatically analyzes recorded interview sessions using video, audio, and text data. The system evaluates verbal and non-verbal communication skills, including speech fluency, facial expressions, eye contact, posture, confidence level, and content relevance. Based on the analysis, the system generates detailed performance scores, personalized feedback, and actionable recommendations to help candidates improve their interview skills.

By leveraging machine learning, computer vision, natural language processing, and speech analysis techniques, the proposed solution aims to provide accessible, objective, and scalable interview assessment for students, job seekers, and professionals.

Expected Outcomes Automated interview assessment Communication and confidence scoring
Eye-contact and facial-expression analysis Speech fluency and filler-word detection Personalized
feedback and recommendations User-friendly dashboard for performance tracking
